

Slope monitor: COVID-19 hospitalisations across EU/EEA

5 countries, steepest modelled rise first. Newest reported week W37 of 2026 (ending 13 Sep); today is W39, so the model is reading 2 weeks behind. Weekly hospital admissions.

MSP (Modelled Smooth Point) = the ensemble's 1- and 2-week-ahead medians extrapolated back one week on a log scale ($t1^{1/2}/t2$).

Left: real levels, own y scale per country, log10. Grey lines are the same calendar weeks 52 and 104 weeks earlier.

Right: each slope re-centred on the mean of its two logs, so the level is gone and only the gradient remains; every slope crosses the dotted zero line mid-way. One shared scale, so steepness compares across countries. Arrowheads mark the week the slope lands on; the rule marks today. The right panel spans +57% per week top to bottom. Its scale is set from the 90th percentile of the drawn slopes; a steeper one is cut at the frame with its gradient intact, not rescaled.

No modelled slope exists for 2 years ago: the hubs did not run in those weeks. The reported column still shows them.

Levels are NOT comparable between countries: national case definitions and denominators differ. Zeros cannot be shown on a log axis.
